Practice Nurse: Noelene Mora

## Background

Risk factors for cardiovascular disease (obesity, diabetes, hypertension, smoking, inactivity, hyperlipidemia) are modifiable, but often tend to be taken seriously only **AFTER** a significant event occurs (heart attack, stroke).

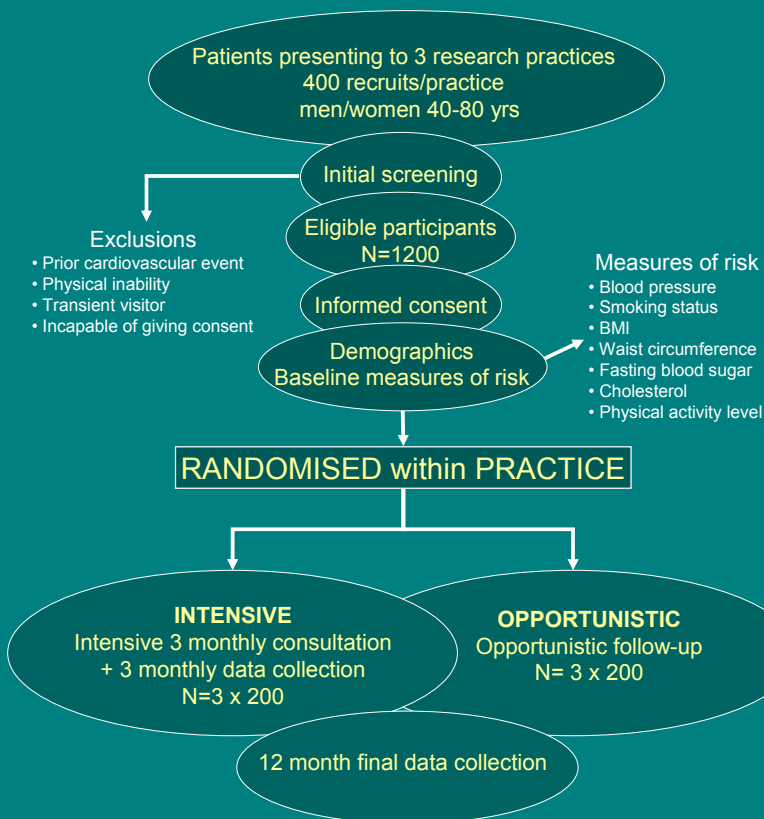

**General practice** offers the opportunity to detect and attempt to modify these risk factors and help reduce subsequent morbidity and mortality.

## Objectives

Document the prevalence of modifiable cardiovascular risk factors in 40 – 80 year old men and women.

Monitor the changes in cardiovascular risk following delivery of intensive and opportunistic intervention strategies at the GP level.

## Methods

## Results/Discussion

To date, 559 participants have completed the study (intensive - n=155, 75 ♀; opportunistic - n=404, 161 ♀).

The figures below represent % of participants outside target for key outcome variables for those that have completed the 12 month study.

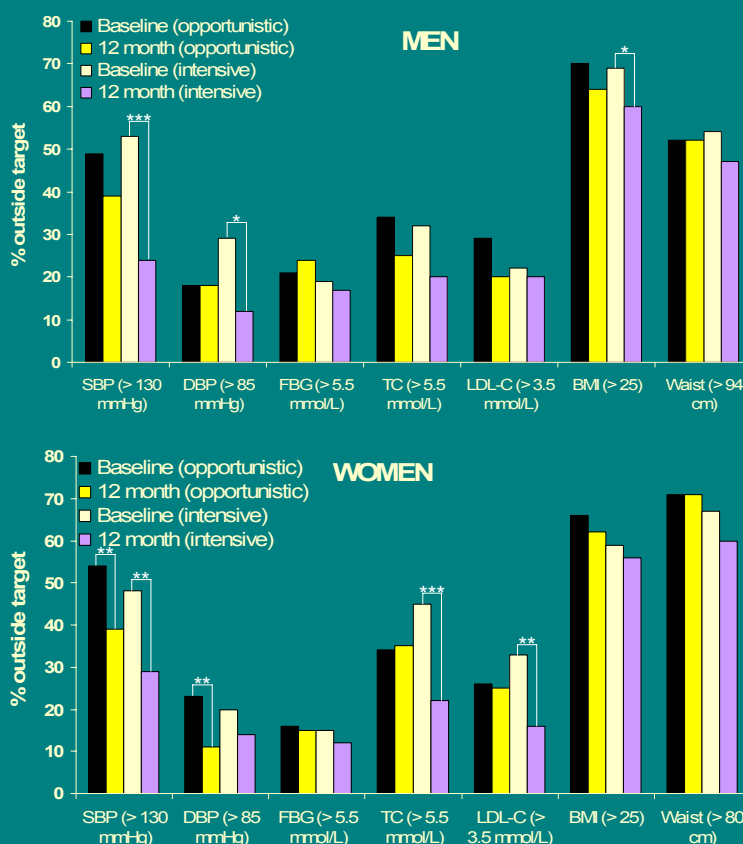

FIGURE NOTE: \*p<0.05, \*\*p<0.01, \*\*\*p<0.001; McNemara  $\chi^2$  using the binomial distribution

## Implications for policy & practice

While a significant proportion of the community are already known to have cardiovascular risk factors, GPs and their practice staff are ideally positioned to assess the extent of this potential morbidity and institute treatment modalities and programmes to reverse and modify them.
