Huperzine A for treatment of cognitive impairment in major depressive disorder: a systematic review of randomized controlled trials

Wei ZHENG¹, Ying-Qiang Xiang²,³, Gabor S. UNGVARI⁴,⁵, Helen F.K. CHIU⁶, Chee H. NG⁷, Ying WANG⁸, Yu-Tao XIANG⁹,*

**Background:** Acetylcholinesterase (AChE) inhibitors have been shown to be effective in treating cognitive impairment in animal models and in human subjects with major depressive disorder (MDD). Huperzine A (HupA), a Traditional Chinese Medicine derived from a genus of clubmosses known as Huperzineserrata, is a powerful AChE inhibitor that has been used as an adjunctive treatment for MDD, but no meta-analysis on HupA augmentation for MDD has yet been reported.

**Aim:** Conduct a systematic review and meta-analysis of randomized controlled trials (RCTs) about HupA augmentation in the treatment of MDD to evaluate its efficacy and safety.

**Methods:** Two evaluators independently searched nine English-language and Chinese-language databases, selected relevant studies that met pre-determined inclusion criteria, extracted data about outcome and safety, and conducted quality assessments and data synthesis.

**Results:** Three low-quality RCTs (pooled n=238) from China were identified that compared monotherapy antidepressant treatment for depression versus combined treatment with antidepressants and HupA. Participants in the studies ranged from 16 to 60 years of age. The average duration of adjunctive antidepressant and HupA treatment in the studies was only 6.7 weeks. All three studies were open label and non-blinded, so their overall quality was judged as poor. Meta-analysis of the pooled sample found no significant difference in the improvement in depressive symptoms between the two groups (weighted mean difference: -1.90 (95%CI: -4.23, 0.44), \(p=0.11\)). However, the adjunctive HupA group did have significantly greater improvement than the antidepressant only group in cognitive functioning (as assessed by the Wisconsin Card Sorting Test and the Wechsler Memory Scale-Revised) and in quality of life. There was no significant difference in the incidence of adverse drug reactions between groups.

**Conclusions:** The data available on the effectiveness and safety of adjunctive treatment using HupA in patients with MDD who are receiving antidepressants is insufficient to arrive at a definitive conclusion about its efficacy and safety. Pooling of the data from three low-quality RCTs from China found no advantage of adjunctive HupA in the treatment of depressive symptoms, but adjunctive treatment with HupA was associated with a faster resolution of the cognitive symptoms that frequently accompany MDD.

**Trial registration number:** CRD42015024796 (http://www.crd.york.ac.uk/prospero/)

**Key words:** depression; meta-analysis; cognitive function; huperzine A; adjunctive treatment

1. Introduction
Major depressive disorder (MDD) is a common psychiatric illness that is often associated with cognitive dysfunction. One hypothesis about the mechanism of cognitive decline in MDD links it to decreasing acetylcholinesterase (AChE) activity of the cholinergic system in the hippocampus, frontal cortex, and septum. Some studies suggest that AChE inhibitors (e.g., donepezil, rivastigmine, galantamine) can ameliorate cognitive impairment in animal models of depression and in humans with MDD. Huperzine A (HupA) is a Traditional Chinese Medicine (TCM) isolated from Huperzineserrata (a genus of clubmosses), also known as ground pines or creeping cedar, in the family Lycopodeiaceae (a family of fern-allies). It is a powerful, highly specific, and reversible inhibitor of AChE. Because of its popularity as a TCM medication in mainland China, extensive clinical experience and research about HupA in China may help clarify the mechanism of action for its potential efficacy in the treatment of MDD. However, to date no systematic review or meta-analysis on HupA augmentation for treatment of MDD has been published. The primary aim of this study was to conduct a systematic review and meta-analysis about the efficacy and safety of HupA in the treatment of MDD based on published RCTs identified by searching international and Chinese databases.

2. Methods
2.1 Types of studies
All publications of randomized controlled trials (RCTs) which reported on the efficacy and/or safety of antidepressants combined with HupA in the treatment of MDD were eligible for inclusion. Case reports/series, observational trials, meta-analyses, and systematic reviews were excluded.

2.2 Outcome measures
The primary outcome measure of interest was cognitive function measured by the Wisconsin Card Sorting Test (WCST) or the Wechsler Memory Scale-Revised, Chinese version (WMS-RC). Key secondary outcomes were improvement in depressive and anxiety symptoms assessed by the Hamilton Depression Rating Scale (HAMD) and the Hamilton Anxiety Rating Scale (HAM A), self-reported quality of life assessed by the General Quality of Life Inventory of the World Health Organization (WHOQOL-100), causes for discontinuation of treatment, and adverse drug reactions measured by the Dosage Record Treatment Emergent Symptom Scale (DOTES). Clinical outcomes were based on intent-to-treat (ITT) analysis.

2.3 Selection of studies
PubMed, PsycINFO, Embase, Cochrane Library databases, the Cochrane Controlled Trials Register, ClinicalTrials.gov, and Chinese databases (WanFang Database, Chinese Biomedical database, and China Journal Net) were searched from the inception of the databases through March 12, 2016 using the following search terms: (Depressive Disorders OR Disorder, Depressive OR Disorders, Depressive OR Neurosis, Depressive OR Depressive Neuroses OR Depressive Neurosis OR Neuroses, Depressive OR Depression, Endogenous OR Depressions, Endogenous OR Endogenous Depression OR Endogenous Depressions OR Depressive Syndrome OR Depressive Syndromes OR Syndrome, Depressive OR Syndromes, Depressive OR Depression, Neurotic OR Depression, Neurotic OR Neurotic Depression OR Neurotic Depressions OR Melancholia OR Melancholias OR Unipolar Depression OR Depression, Unipolar OR Depressions, Unipolar OR Unipolar Depressions) AND (Huperzine A OR Huperzine OR HupA) AND (randomized controlled trial OR controlled clinical trial OR randomized OR placebo OR drug therapy OR randomly OR trial OR groups). We also hand-searched reference lists from identified and relevant review articles for additional studies and contacted authors for unpublished data.

2.4 Data extraction
Two authors (ZW and XYQ) independently conducted the literature search and extracted the data. Any disagreement was resolved by a third author (XYT). Data presented only in graphs and figures were extracted whenever possible. Authors were contacted to obtain missing information or clarification if possible. If cases were from multicenter studies, whenever possible, data were extracted separately for each center.

2.5 Statistical methods
We used RevMan (version 5.1.7.0) in this meta-analysis according to the recommendations of the Cochrane Collaboration. For continuous data, weighted mean difference (WMD) with 95% CI was used to compare groups, and for dichotomous data, risk ratio (RR) with 95% confidence intervals (CIS) were computed to compare groups. The I^2 statistic assessed statistical heterogeneity between the three studies: when I^2≤50%, a random effects model was used; otherwise, a fixed effect model was employed. All analyses were two-tailed with alpha set at 0.05.

2.6 Risk of bias assessment
The methods of random sequence generation (selection bias), allocation concealment (selection bias), blinding of participants and personnel (performance bias), blinding of outcome assessment (detection bias), incomplete outcome data (attrition bias), selective reporting (reporting bias), and other biases were assessed using the Risk of Bias (ROB) scale developed to assess RCTs by the Cochrane Collaboration.
3. Results

3.1 Results of the literature search
The search yielded 54 potentially relevant articles, of which four articles were published in English and 50 in Chinese. Of the 54 studies, 3 RCTs met the inclusion criteria.\(^{[20-22]}\) As shown in Figure 1, the total number of subjects included in the three studies was 238, with 119 receiving an antidepressant augmented with HupA and 119 only receiving an antidepressant.

3.2 The characteristics of included studies
As shown in Table 1, all three RCTs\(^{[20-22]}\) were conducted in China and used the criteria of the Chinese Classification of Mental Disorders, 3rd edition (CCMD-3)\(^{[23]}\) to diagnose depression. Males accounted for 45.4\% of the sample (range 30\% to 58\% in the three studies), the weighted mean age of participants was 29.6 (range 16-60) years; and the weighted mean duration of illness was 3.3 (range 1.2 to 5.2) years. The weighted mean duration of the treatment trial reported in the studies was 6.7 (range 6-8) weeks. None of the studies were supported by pharmaceutical companies.

3.3 Assessment of risk of bias
The risk of different types of biases of the three studies is shown in Table 2. Two studies\(^{[21-22]}\) mentioned “random” assignment without a description of the method of randomizing, and one RCT\(^{[20]}\) was rated as high risk of selection bias because patients were
classified into two groups according to the order of admission. None of the studies were blinded so the risk of allocation bias, performance bias, and detection bias were high. The studies reported the outcomes of all enrolled subjects, so the risk of attrition bias was low; but in the absence of study registration materials it was impossible to determine whether or not there was selective reporting (i.e., reporting bias). There was no evidence of other types of biases (e.g., drug company sponsorship of the study). Overall, all three studies were considered at high risk of bias and, thus, relatively low-quality studies.

Because there were only three RCTs included in the meta-analysis, publication bias could not be tested.24

3.4 Changes in severity of depressive symptoms

In all three studies there were differences between groups in changes of the total HAMD score over
the study period. As shown in Figure 2, one of the studies\[22\] reported a significantly greater reduction of depressive symptoms (based on the HAMD) when adjunctive HupA was provided to patients with MDD being treated with antidepressants, but the other two studies did not find a significant advantage of adjunctive treatment with HupA. When pooling the three studies in a random effects meta-analysis, there was no statistically significant difference in the improvement of depressive symptoms between MDD patients who only received antidepressants and those who received antidepressants and adjunctive HupA.

### 3.5 Cognitive results

The other results from the three studies are shown in Table 3. Only two studies\[20,21\] assessed the cognitive effects of the treatment. Both studies reported a significant advantage of using adjunctive HupA. In one study,\[21\] memory functioning at the end of the 8-week trial was better in patients taking antidepressants with adjunctive HupA than in those who were only taking antidepressants. In another study,\[20\] several measures of executive functioning derived from the WCST were significantly better at the end of the 6-week trial in depressed patients taking antidepressants with adjunctive HupA. These cognitive outcome measures were quite different so it was not possible to pool the results of the two studies into a meta-analysis.

### 3.6 Other results

The level of anxiety was only assessed in one of the studies.\[22\] Based on the total score of the HAMA at the end of the 6-week trial, there was no significant difference in the severity of anxiety symptoms between the two groups (Table 3).

Only one study\[20\] assessed quality of life. As measured by WHOQOL-100,\[15\] quality of life was significantly better at the end of the trial in individuals who received combined treatment with antidepressants and HupA (Table 3).

Only one study\[22\] assessed adverse reactions. The study assessed adverse events using the DOTES\[16\] which considers tachycardia, dysuria, electrocardiographic abnormality, dry mouth, drowsiness, nausea, constipation, blurred vision, and insomnia. It found no difference in the prevalence of adverse events between the two treatment groups.

None of the included RCTs reported the rate or causes of treatment discontinuation.

### 4. Discussion

#### 4.1 Main finding

Despite an extensive review of both English-language and Chinese-language literature, we only identified three RCTs that assessed the potential benefit of adjunctive HupA when treating individuals with depression who are currently using antidepressants. All three studies were open label and the outcome evaluation in the trials was not blinded, so the overall strength of the studies was rated as 'poor'. The pooled sample from the three studies, all of which were published in Chinese, was 238 individuals, but it was only possible to conduct a meta-analysis for the results related to changes in depressive symptoms because other outcomes of interest (e.g., cognitive changes, quality of life changes, etc.) were only considered in one or two of the studies. Overall, the results suggest that adjunctive treatment with HupA over 6 to 8 weeks in patients with depression who are currently taking antidepressants does not
Table 3. Comparison of cognitive function, anxiety, and quality of life in patients with depression at end of course of treatment with either antidepressants and adjunctive HupA (experimental group) or with antidepressants alone (control group)

WMS-RC, Wechsler Memory Scale-Revised, Chinese version[12]
HAMA, Hamilton Anxiety Rating Scale[14]
WHOQOL-100, General Quality of Life Inventory of World Health Organization[15]

result in a better reduction of depressive symptoms, but it does appear to lead to less cognitive impairment in depressed individuals and, possibly, to a better self-reported quality of life for depressed individuals.

4.2 Limitations
The small number of studies identified and the limited measures employed in the identified studies made it impossible to conduct a full meta-analysis, so we could not do a sensitivity analysis or subgroup analyses, and we could not construct a funnel plot to assess potential publication bias. Specifically, there were not enough studies with data on cognitive functioning to conduct a meta-analysis of this important outcome. Moreover, the relatively low quality of the available studies (open label, non-blinded) and the relatively short duration of the studies (from 6 to 8 weeks) means that the findings that were significant – the benefit of HupA augmentation for cognitive functioning and quality of life in depressed patients – are not robust; they need to be replicated in larger, methodologically more rigorous RCTs that follow participants for much longer.

4.3 Importance
Despite the limited number of RCTs identified and the methodological limitations of the identified studies,[23] this review does provide some support for the suggestion that AChE inhibitors such as HupA can ameliorate the cognitive decline that is often associated with depression and, possibly, improve the quality of life of individuals being treated for depression with antidepressant medications. Similar to our findings, a recent meta-analyses[26] found that adjunctive HupA is an effective choice for improving cognitive function in individuals with schizophrenia. The mechanism of action of HupA in improving cognitive functioning (or preventing cognitive decline) remains unknown, but given the importance of cognitive impairment in a wide range of mental disorders, further work in this promising area is merited.

Funding
The study was supported by the Start-up Research Grant (SRG2014-00019-FHS) and the Multi-Year Research Grant (MYRG2015-00230-FHS) from the University of Macau. Trial registration number: CRD42015024796 (http://www.crd.york.ac.uk/prospero/)

Conflict of interest statement
The authors report no conflict of interest in conducting this study and preparing the manuscript.

Authors’ contribution
WZ designed the study and was assisted by YQX and YTX in the search for papers, data extraction, and analysis. WZ and YTZ drafted the manuscript. GSU, HFKC, CHN, and YW made critical revisions to the manuscript. All authors approved the final version for publication.
石杉碱甲对重度抑郁症患者认知功能障碍的治疗：一项随机对照试验的系统综述

郑伟, 向应强, Ungvari GS, Chiu F.K. H, Ng H. C, 王颖, 项玉涛

背景：乙酰胆碱酯酶 (Acetylcholinesterase, AChE) 抑制剂在重性抑郁障碍 (Major Depressive Disorder, MDD) 的动物模型和人类患者中已被证实可以有效地治疗认知障碍。石杉碱甲 (Huperzine A, HupA) 是一种来自被称为蛇足石杉 (Huperzineserrata) 的石松属传统中医药，是一种强有力的 AChE 抑制剂，已被用于抑郁症的辅助治疗，但有关其疗效和安全性的明确结论。汇集中国内 3 项低质量的RCT数据没有发现采用辅助使用HupA治疗抑郁症症状的优势，但辅助使用HupA与更快速改善经常伴随MDD出现的认知症状相关。

结论：有关在治疗抑郁症的MDD患者使用HupA辅助治疗的疗效和安全性的可获取数据不足，难以得出有关其疗效和安全性的明确结论。汇集中国内3项低质量的RCT数据没有发现采用辅助使用HupA治疗抑郁症症状的优势，但辅助使用HupA与更快改善经常伴随MDD出现的认知症状相关。
