Abstract

Prostate cancer is one of the most prevalent cancers in men. It is critical to identify and characterize oncogenes that drive the pathogenesis of human prostate cancer. The current study builds upon previous research showing that a disintegrin and metalloproteinase (ADAM)28 is involved in the pathogenesis of numerous cancers. Our novel study used overexpression, pharmacological, and molecular approaches to investigate the biological function of ADAM28 in human prostate cancer cells, with a focus on cell proliferation and migration. The results of this study provide important insights into the role of metalloproteinases in human prostate cancer.

The expression of ADAM28 protein levels was assessed within human prostate tumors and normal adjacent tissue by immunohistochemistry. Immunocytochemistry and western blotting were used to assess ADAM28 protein expression in human prostate cancer cell lines. Functional assays were conducted to assess proliferation and migration in human prostate cancer cells in which ADAM28 protein expression or activity had been altered by overexpression, pharmacological inhibition, or by siRNA gene knockdown.

The membrane bound ADAM28 was increased in human tumor biopsies and prostate cancer cell lines. Pharmacological inhibition of ADAM28 activity and/or knockdown of ADAM28 significantly reduced proliferation and migration of human prostate cancer cells, while overexpression of ADAM28 significantly increased proliferation and migration.

ADAM28 is overexpressed in primary human prostate tumor biopsies, and it promotes human prostate cancer cell proliferation and migration. This study supports the notion that inhibition of ADAM28 may be a potential novel therapeutic strategy for human prostate cancer.

Abbreviations: ADAM = a disintegrin and metalloproteinase, CTGF = connective tissue growth factor, DHT = dihydrotestosterone, IGF = insulin-like growth factor, IGFBP-3 = IGF binding protein-3, IL-6 = interleukin 6, RPMI = Roswell Park Memorial Institute, VEGF = vascular endothelial growth factor, VWF = von Willebrand factor.

Keywords: ADAM28, metalloproteinase, migration, proliferation, prostate cancer

1. INTRODUCTION

Prostate cancer is the 2nd most common cancer in men, and the 5th most common cause of cancer-related deaths in men worldwide.^[1] The age-adjusted incidence of prostate cancer has risen in line with an increase in the number of men being tested and improvements in widespread diagnostic testing.^[1] Current therapies for prostate cancer such as androgen ablation result in a reduction in symptoms seen in around 70% to 80% of patients with advanced prostate cancer.^[2] However, tumors can relapse within 2 years and transform into an incurable androgen-independent state,^[3] and there are other disadvantages.^[4,5] It is therefore important to develop alternative treatment options, which aim to reduce the proliferation and progression of prostate cancer cells.

A disintegrin and metalloproteinases (ADAMs) are a gene family of transmembrane and/or secreted proteins which regulate cell phenotype via effects on cell adhesion, migration, proteolysis, and signaling.^[6–9] Numerous ADAM family members have previously been linked with the malignant progression of human prostate cancer. Fritzsche et al^[10] report that ADAM8 expression is associated with increased Gleason scores and positive node status. ADAM9 expression is significantly higher in prostate cancer tissue than normal prostate tissue^[11] and inhibition of

ADAM9 expression in prostate cancer enhanced prostate cancer sensitivity to chemotherapy and radiation.^[112] Knockdown of ADAM10 reduced proliferation of prostate cancer cells, suggesting that ADAM10 may contribute to the progression of prostate cancer by increasing proliferation.^[113] McCulloch et al^[144] report that ADAM12 expression is significantly higher in prostate cancer tissues than normal prostate tissue. ADAM15 has been shown to contribute to the metastatic progression of human prostate cancer through the binding of its disintegrin domain to various integrins.^[115] Finally, Xiao et al^[116] demonstrated that ADAM17 increased the invasive capacity of prostate cancer cells by targeting matrix metalloproteinases (MMPs) 2 and 9. Interestingly, in contrast to other ADAM family members, our team have elucidated that ADAM19 is a protective biomarker in human prostate cancer.^[117] Herein, we advance current knowledge by focusing on the potential role of the metalloproteinase ADAM28 in human prostate cancer to determine if it could be a new target for intervention.

ADAM28 exists in 2 isoforms: a secreted soluble form (ADAM28s) and a membrane bound form (ADAM28m).^[118] Both forms contain the metalloproteinase and disintegrin domains, which function in proteolysis and cellular adhesion, respectively. ADAM28 is expressed and synthesized in its precursor form (zymogen form-proADAM28) by lymphocytes and some cancer cells.^[118] Studies have suggested that the prodomain is required to maintain the latency of metalloproteinases,^[119] and proADAM28 is activated by matrix metalloproteinases-7 via the removal of its prodomain.^[118] The metalloprotease domain facilitates the degradation of several substrates, including tumor necrosis factor- α ^[120] and others that are discussed in more detail below. ADAM28's disintegrin domain is reported to bind the integrins $\alpha 4\beta 1$, $\alpha 4\beta 7$, and $\alpha 9\beta 1$ on lymphocytes in an activation-dependent manner. The leukocyte integrin interaction with ADAM28 proposes a potential attachment and cleavage role for ADAM28 in inflammation and immunity.^[121,122]

ADAM28 cleaves substrates known to be involved in metastasis including insulin-like growth factor (IGF) binding protein-3 (IGFBP-3),^[123] connective tissue growth factor (CTGF),^[124] and von Willebrand factor (VWF).^[125] High levels of the mitogen IGF-I and low levels of IGFBP-3 are associated with a higher risk of prostate cancer in men.^[126] Previous studies have indicated that IGF-IR blockade reduces the invasive activity of PC-3^[127] and DU145^[128] human prostate cancer cells. IGFBP-3 degradation by ADAM28 may play vital roles in carcinoma cell proliferation and metastasis.^[19] We have previously demonstrated that ADAM28 cleaves VWF^[125] and high levels of ADAM28 expression are implicated in the inactivation of proapoptotic VWF. Studies from our team have also demonstrated that overexpression of ADAM28 in human breast carcinoma cells was positively associated with enhanced expression of both vascular endothelial growth factor (VEGF) and CTGF.^[124]

ADAM28 is suggested to be implicated in proliferation, migration, and invasion in nonsmall cell lung cancer,^[129] breast cancer tissue,^[123] bladder cancer,^[130] head and neck cancer,^[131] and B-cell acute lymphoblastic leukemia.^[132] Given that ADAM28 has an oncogenic effect in other cancers and cleaves substrates with known association with cancer metastases, these findings provide a strong foundation for the investigation of ADAM28 in the pathogenesis of human prostate cancer. Our study aimed to determine the importance of ADAM28 in human prostate cancer, and whether it could be further progressed as a potential therapeutic target.

2. METHODS

2.1. Clinical samples

Human prostate tumor biopsies (n=8) and paired adjacent benign prostate tissue samples (n=8) were obtained from Dr Ronald Cohen (Urology, Perth, Western Australia). Tissue samples were obtained with consent (institutional human ethics application number EC 2008/118). Informed consent was obtained from patients and a high standard of ethics was applied in carrying out the investigations. Full face sections of prostate cancer tissue were immunostained for ADAM28.

2.2. Immunohistochemistry

Tissue was fixed in glutaraldehyde (2.5%) and paraffin embedded. Sections were deparaffinized through xylene, rehydrated through graded alcohols to distilled water, and subjected to antigen retrieval in EDTA pH 8.0 under pressure. After blocking endogenous peroxidase activity with hydrogen peroxide, the mouse antihuman ADAM28 antibody (297-2F3)^[123] was applied at 1:500 for 60 minutes. A horse-radish peroxidase labeled polymer conjugated with rabbit/mouse secondary antibodies (DAKO envision+) was then incubated for 30 minutes. Sections were visualized with diaminobenzidine (DAKO) followed by a light counterstain with hematoxylin.

2.3. Cell culture

All cells were purchased from the American Type Culture Collection (Manassas, VA). LNCaP and DU145 cells were cultured in a 6 well cell bind plate (Costar) containing Roswell Park Memorial Institute (RPMI)-1640 media (Sigma-Aldrich, Steinheim, Germany) with 10% FCS and 2% penicillin/streptomycin (Invitrogen, USA). They were maintained and grown at 37°C, in 95% O₂/5% CO₂. RWPE1 cells were cultured in a 6 well cell bind plate containing Keratinocyte-serum-free medium (Life Technologies) with 2% penicillin/streptomycin (Invitrogen).

2.4. Determination of protein expression

Cell harvesting and western blots were conducted as previously described.^[120]

2.5. Antibodies

The primary antibodies used for western blot analysis were as follows: anti-ADAM28 mouse monoclonal antibody (297-2F3) specific to the ADAM28 metalloproteinase domain^[129]; anti-ADAM28 rabbit polyclonal antibody specific to the intracytoplasmic domain (#ab39875, Abcam, Cambridge, USA); mouse IgG isotype control (#sc-2025, Santa Cruz, Texas, USA); mouse anti- β -actin antibody (Millennium), and rabbit anti-prostate specific antigen polyclonal antibody (#A0562, Dako-Cytomation). The secondary antibodies, antimouse IRDYE 800 and antimouse IRDYE 680 were purchased from Millennium.

2.6. Transfection of plasmids into cells

Transfection was conducted as previously described.^[17] Transfected cells were used for immunocytochemistry to evaluate ADAM28 overexpression, proliferation, and migration studies. The plasmid vectors utilized were pCMV Tag4A ADAM28 and pCMV Tag4A empty vector.^[133]

2.7. Immunocytochemistry

Immunocytochemistry was conducted on transfected cells as previously described.^[17]

2.8. Enzyme-linked immunosorbent assay (ELISA)

Human IGF-I and interleukin-6 (IL-6) were measured in cell free culture supernatants (collected from cells transfected for 48 hours) using commercially available ELISA kits as per manufacturer instructions (ELISAKIT.com).

2.9. ADAM28 knockdown utilizing short-interfering RNA (siRNA)

In all siRNA experiments, cells were seeded into 12 well cell culture dishes, and transfections were conducted using XtremeGENE HP DNA transfection reagent (Roche). ADAM28 was knocked down using Silencer Select siRNA A28 siRNA 2 (#s21323, Applied Biosystems). The sequences are as follows:

Sense: CGACUAUUCUUGCAAGUG/Antisense: ACACUUGCAAGAAUAGUCG

siRNA (10 nM) was added to 0.25×10^5 cells/mL suspended in 100 μ L of RPMI-1640 growth media and incubated for 48 hours (cells were free of streptomycin/penicillin for 4 hours). A Cy3 labeled double-stranded transfection control (scrambled siRNA; IDT) was used at 10 nM as a negative control.

2.10. Real time PCR analysis

Cells grown in 12 well plates were directly lysed with 200 μ L/well of TRIzol Reagent (Invitrogen). RNA was isolated from the cells in accordance to manufacturer's instructions. RNA samples were DNase treated using the RQ1 RNase-Free DNase (Cat# M6101, Promega). DNase-treated RNA was mixed with a master mix prepared from the TaqMan Reverse Transcription Reagents kit (Applied Biosystems, Branchburg, NJ). The samples were then reverse transcribed in the Gene Amp PCR system 9700 Thermocycler (Applied Biosystems).

To quantitate the relative expression of genes of interest from extracted RNA samples, the cDNA samples were subjected to real time PCR analysis. PCR reactions were composed of cDNA sample, TaqMan master mix, DEPC-treated water, and 20X Taqman assay from Life Technologies (HPRT [Hs02800695_m1] or human ADAM28 [Hs00248020_m1]). The cDNA samples were amplified using the Rotor Gene-2000 real-time PCR thermal cycler (Corbett Research). Real time PCR data were analyzed using the comparative critical threshold (also known as threshold cycle; C_T) method.

2.11. Pharmacological inhibition of ADAM28

Cells were seeded into 2 separate treatments of either the dimethyl sulfoxide (DMSO) or the ADAM28 inhibitor KB-R7785 (1–5 μ M) diluted in DMSO.^[23] Cells were then used for proliferation and migration assays.

2.12. DHT treatment of prostate cancer cells

Prostate cancer cells were treated with 10 nM dihydrotestosterone (DHT) for 24 hours.

2.13. MTS assay

Cells were suspended in RPMI-1640 medium containing 10% FCS and 2% streptomycin/penicillin. After counting cells, they were

resuspended (0.125×10^5 cells/mL) and 100 μ L of cells were added to the center of the wells of a 96-well flat bottom culture plate. The medium was carefully aspirated on days 1, 3, 5, or 7 and replaced with 100 μ L RPMI-1640 medium containing 10% FCS and 2% streptomycin/penicillin containing 20 μ L of MTS assay reagent (Promega). Proliferation was determined by the formation of a colored formazan product. Plates were read at 490 nm using a plate reader. The Olympus fluorescent microscope was used at each required time point to image cells. The MTS assay result was supported by cell count data in some experiments.

2.14. Transwell migration assays

Cell migration was assessed by an assay using transwells fitted with uncoated 8 μ m pore size polycarbonate membranes. Inserts containing 100 μ L of FCS-free growth medium were placed into wells of a 24 well plate possessing 10% FCS containing medium. The transwell devices were left to equilibrate at 37°C for 1 hour. The FCS free growth medium was then replaced with new FCS-free growth media containing LNCaP cells at a density of 0.25×10^5 cells/mL and incubated at 37°C for 1 and 3 days. Cells attached to the bottom surface of the membrane at 2 and 3 days post-seeding were fixed using methanol, followed by hematoxylin staining. The membrane was then washed 3 times and cells remaining on the upper surface of the membrane were removed using a cotton swab. The bottom of the membrane was then visualized using light microscopy at 200 \times magnification. Five random high powered fields of view were captured and used to analyze migration. Migrated cells were distinguished by their dark blue opaque appearance.

2.15. Western blotting for endogenous IGFBP-3 cleavage in DU145 cells

DU145 cells were starved in 0.1% serum-containing medium overnight. The following day, cells were cultured in 0.1% serum containing medium in the absence or presence of 1 μ M KB-R7785 for 30 minutes before adding IGF-I (100 ng/mL). Cells were then cultured for 24 hours. Serum-free conditioned cell culture supernatants were concentrated using the Biomax 5k NmwL membrane (Millipore). The western blot for IGFBP-3 cleavage was conducted on concentrated cell culture medium as previously described.^[23] The rabbit anti-human IGFBP-3 antibody was a kind gift from Rob Baxter (Kolling Institute).

2.16. Statistical data analysis

Statistical analysis was carried out with the assistance of Professor Max Bulsara (The University of Notre Dame) using IBM SPSS statistics software. Nonparametric *t* tests (Mann–Whitney) were performed to compare mediums of sample medium values when “n” was greater than 3. Statistical significance was determined if the probability of the null hypothesis was less than 0.05 ($P \leq 0.05$). IBM SPSS statistics was used to plot all graphs.

3. RESULTS

3.1. Human prostate carcinoma tissue displays elevated ADAM28 expression

Human prostate tumor biopsies and paired adjacent benign prostate tissue samples were immunostained for ADAM28 expression. The prostate tumor biopsies possessed Gleason

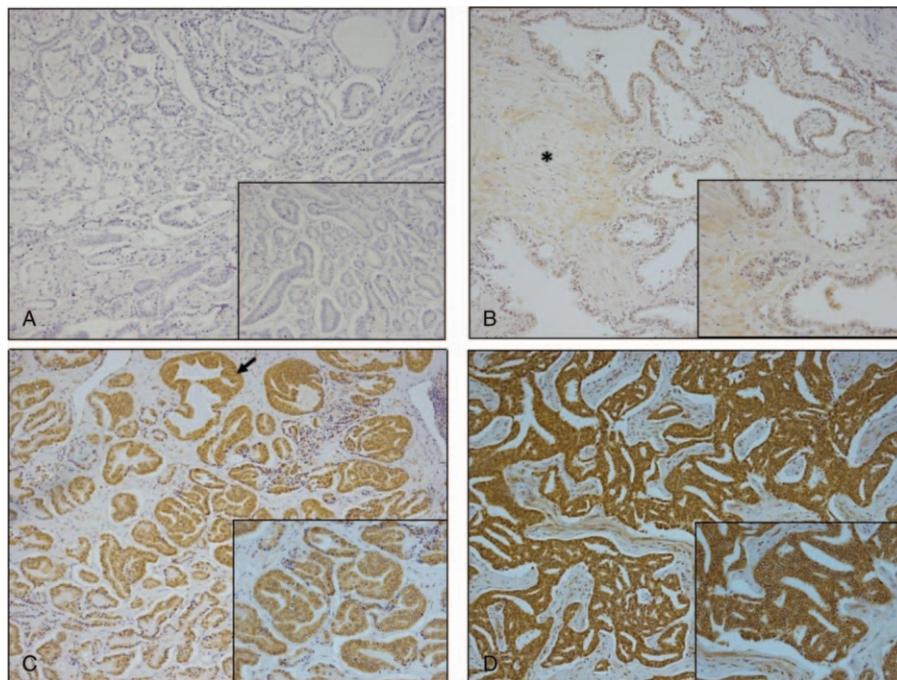

Figure 1. Immunostaining of a disintegrin and metalloproteinase (ADAM)28 in human prostate cancer. (A) non-immune mouse IgG immunostaining of human prostate tumor (Gleason grade 3+4=7), (B) ADAM28 immunostaining (brown) of benign prostate, (C) prostate tumor (Gleason grade 3+4=7), and (D) prostate tumor (Gleason grade 4+4=8). All main photomicrographs are 100× magnification while insets are 300× magnification. Asterisk (panel B) indicates stroma and arrow (panel C) indicates glandular hyperplasia.

grades ranging from 7 to 8. First, prostate tumor samples demonstrated negligible background immunoreactivity staining when they were stained with non-immune mouse IgG1 (Fig. 1A). However, we found that human prostate carcinoma samples have increased ADAM28 expression (Fig. 1C, D) indicated by brown staining when compared to normal human prostate tissue (Fig. 1B). These data provided an incentive to explore the effects of androgen on ADAM28 expression, which we were able to evaluate in prostate cancer cells.

We also obtained normal and prostate tumor (Gleason score 9) tissue for the assessment of ADAM28 protein expression by western blotting. The active membrane-bound form of ADAM28 (55 kDa) is elevated 2-fold in tumor tissue compared to normal

prostate tissue (Supplementary Fig. 1, <http://links.lww.com/MD/B318>).

3.2. ADAM28 expression is increased in human prostate cancer cells after dihydrotestosterone treatment

As androgen is a major driver in prostate cancer, we examined whether ADAM28 expression is enhanced by exposure to androgens, such as DHT. When androgen sensitive human LNCaP prostate cancer cells were treated with and without DHT, ADAM28 protein expression was increased greater than 3-fold in the presence of DHT (Fig. 2). This was mirrored by an expected increase in the expression of prostate specific antigen, the positive

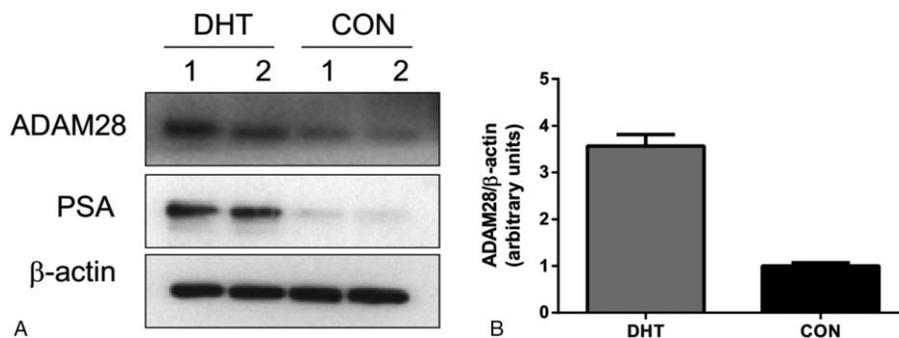

Figure 2. ADAM28 protein expression is increased in the presence of DHT in androgen responsive human LNCaP prostate cancer cells. LNCaP cells were either treated with DHT (10nM) or untreated (CON) for 24 hours, in duplicate. (A) Western blot indicates that the presence of DHT increases the expression of both ADAM28 and PSA when compared with the untreated controls. (B) Quantitation of ADAM28 expression. ADAM= a disintegrin and metalloproteinase, DHT= dihydrotestosterone, PSA=prostate specific antigen.

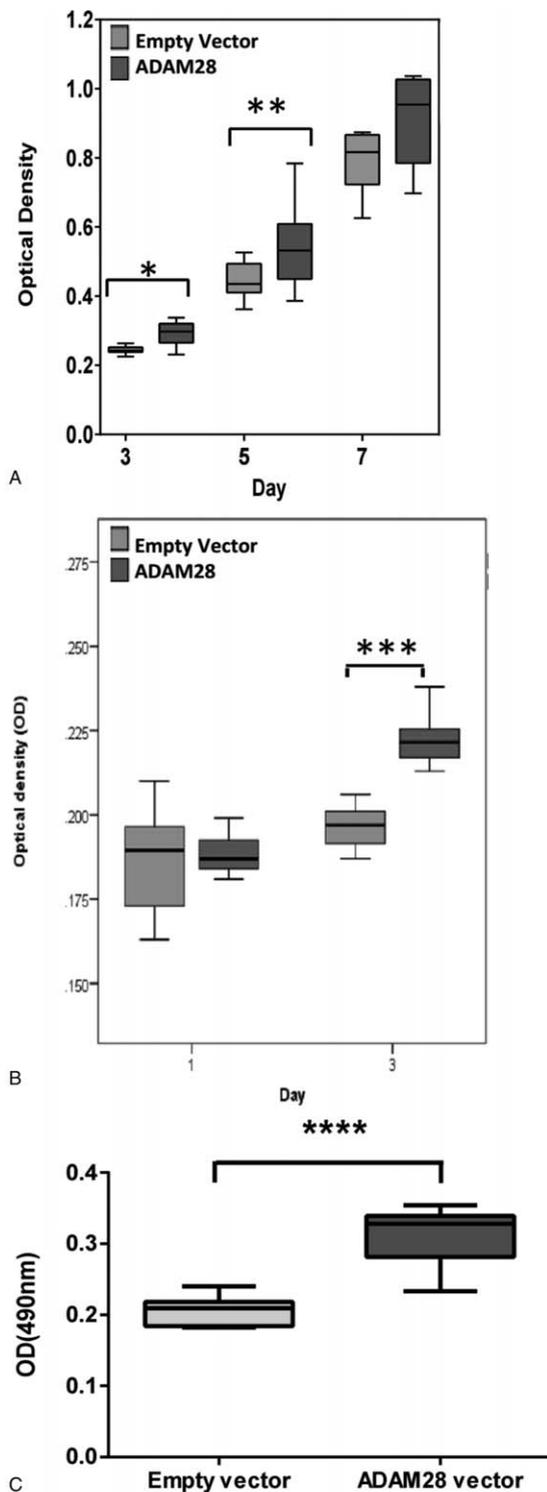

Figure 3. Overexpression of ADAM28 in human prostate cancer cells and normal prostate epithelial cells promotes proliferation. DU145 (A), LNCaP (B), and RWPE1 (C) cells were either transiently transfected with empty vector (pCMV-Tag4a) or an ADAM28 expressing vector (pCMV-Tag4a ADAM28). Proliferation of cells was measured utilizing MTS reagent and read at 490 nm ($*P < 0.02$; $**P < 0.012$; $***P < 0.001$; $****P = 0.0001$, Mann-Whitney) $n = 6-16$. Data are presented as a box and whisker plot. ADAM=a disintegrin and metalloproteinase.

control, in the DHT treated samples compared to the controls. Taken together, these data suggest that not only is ADAM28 expression associated with more poorly differentiated tumors, it may be regulated by androgen in a feed-forward manner.

3.3. ADAM28 overexpression studies

We next evaluated the functional effects of transient overexpression of ADAM28 in human prostate carcinoma cells (DU145 and LNCaP). A plasmid encoding human ADAM28 cDNA was transiently transfected into the cells, resulting in ADAM28 overexpression in both cell lines after 48 hours. Immunohistochemistry was performed on the cells using anti-ADAM28 antibody (297-2F3). ADAM28 expression was identified by strong brown cytoplasmic staining (Supplementary Fig. 2, <http://links.lww.com/MD/B318>). The over-expressed ADAM28 was detected as the active (55 kDa) membrane bound form (Supplementary Fig. 3, <http://links.lww.com/MD/B318>).

We next explored the effect of ADAM28 overexpression on proliferation of DU145 and LNCaP human prostate cancer cell lines compared to normal RWPE1 prostate epithelial cells. We show by MTS cell proliferation assay that overexpression of ADAM28 promotes proliferation of DU145 (Fig. 3A), LNCaP (Fig. 3B), and RWPE1 cells (Fig. 3C). This result also confirmed that overexpression of ADAM28 stimulates proliferation of human normal prostate epithelial and cancerous prostate cells.

3.4. Inhibition of ADAM28 reduces IGFBP-3 cleavage, while overexpression of ADAM28 promotes IGF-I, but not IL-6 release from human prostate carcinoma cells

Our previous studies highlight that the ADAM inhibitor KB-R7785 is highly capable of inhibiting ADAM28-mediated cleavage.^[20] We now show that KB-R7785 may reduce IGFBP-3 cleavage (22 kDa product) in DU145 prostate cancer cells (Fig. 4A).

Previous studies have shown that IGF-I and IL-6 influence the invasiveness of prostate cancer cells, supporting the concept that IGF-I and IL-6 are identifiable predictors of prostate cancer prognosis. This is particularly relevant as ADAM28 is already known to be a potential upstream mediator of IGF-I release from cells.^[23] An IGF-I ELISA performed on supernatant from DU145 cells that were transiently transfected with empty vector or ADAM28 vector revealed that overexpression of ADAM28 significantly increased IGF-I release (Fig. 4B). However, IL-6 ELISA data showed that ADAM28 overexpression does not affect IL-6 release (Fig. 4C). Therefore, in a human prostate cancer setting, the liberation of IGF-I appears to be regulated by ADAM28.

3.5. Pharmacological inhibition of ADAM28 activity by KB-R7785 attenuates proliferation of human prostate carcinoma cells

Given that overexpression of ADAM28 can drive the proliferation of human prostate cancer carcinoma cells, we next investigated the effect of inhibition of ADAM28 activity by KB-R7785. Pharmacological inhibition of ADAM28 by KB-R7785 significantly reduced the proliferation of DU145 (Fig. 5A) and LNCaP (Fig. 5B) human prostate cancer cells. These results provide further confirmation that ADAM28 plays a role in promoting human prostate carcinoma cell proliferation.

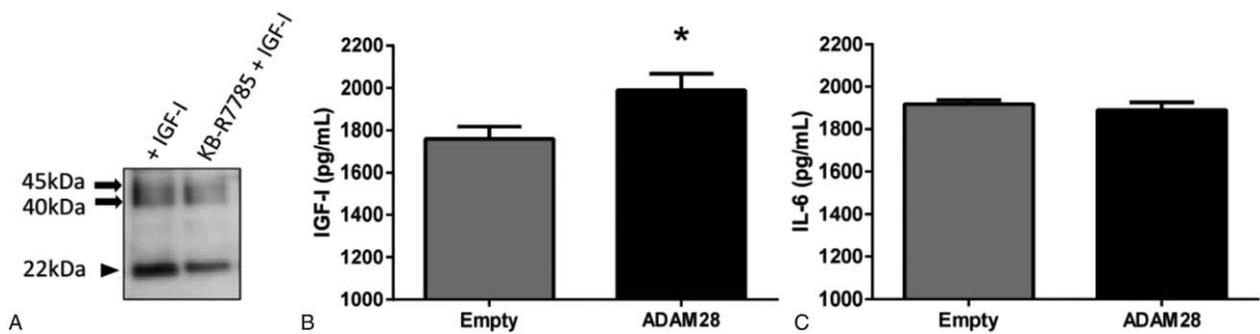

Figure 4. Inhibition of ADAM28 reduces IGFBP-3 cleavage, while overexpression of ADAM28 in DU145 human prostate cancer cells elevates IGF-1, but not IL-6 expression. (A) IGFBP-3 cleavage is inhibited by the ADAM inhibitor KB-R7785. (B) IGF-1 is significantly increased when ADAM28 is overexpressed. (C) There is no change in the expression of IL-6 when ADAM28 is over expressed; $n=6-9$ samples per treatment. Data are presented as mean \pm SEM. * $P=0.03$. ADAM = a disintegrin and metalloproteinase, IGF = insulin-like growth factor, IGFBP-3 = IGF binding protein-3, IL-6 = interleukin 6, SEM = standard error of mean.

3.6. siRNA knockdown of ADAM28 in human prostate cancer cells

We also assessed the effect of knocking down ADAM28 using siRNA. Fluorescent microscopy of LNCaP prostate carcinoma cells transfected with Cy3-labeled (red) scrambled siRNA confirmed high transfection efficiency (Supplementary Fig 4A and B, <http://links.lww.com/MD/B318>). Real-time PCR for ADAM28 was performed to confirm ADAM28 siRNA-mediated knock down of ADAM28 mRNA (Supplementary Fig 4C, <http://links.lww.com/MD/B318>). Importantly, we observed a significant decrease in the proliferation of LNCaP cells treated with ADAM28 siRNA relative to Cy3-labeled scrambled siRNA (Fig. 5C). This result was also repeated with a 2nd ADAM28 siRNA (data not shown).

3.7. Human prostate cancer cell migration is reduced by ADAM28 inhibition

Finally, we examined the role of ADAM28 in prostate carcinoma cell migration using Transwell chambers. We performed a migration assay using LNCaP cells treated with KB-R7785 or

RWPE1 normal epithelial cells transfected with ADAM28 vector. When ADAM28 activity was inhibited by KB-R7785 for 3 days, migration of the LNCaP cells was significantly reduced compared to DMSO treated cells (Fig. 6A). Conversely, we found that RWPE1 cells transfected with ADAM28 vector exhibited significantly increased migration compared to cells transfected with empty vector after 2 days (Fig. 6B). Therefore, in addition to regulating prostate cancer cell proliferation, ADAM28 may mediate some aspects of prostate cancer cell migration.

4. DISCUSSION

This study highlights that ADAM28 is overexpressed in human prostate cancer tissue biopsies. Furthermore, we demonstrated that ADAM28 promotes proliferation and migration of human prostate carcinoma cells. Interestingly, overexpression of ADAM28 in human prostate carcinoma or normal prostate epithelial cells enhanced cellular proliferation and migration, while inhibition with an ADAM28 inhibitor or siRNA silencing of ADAM28 reduced cellular proliferation and migration of

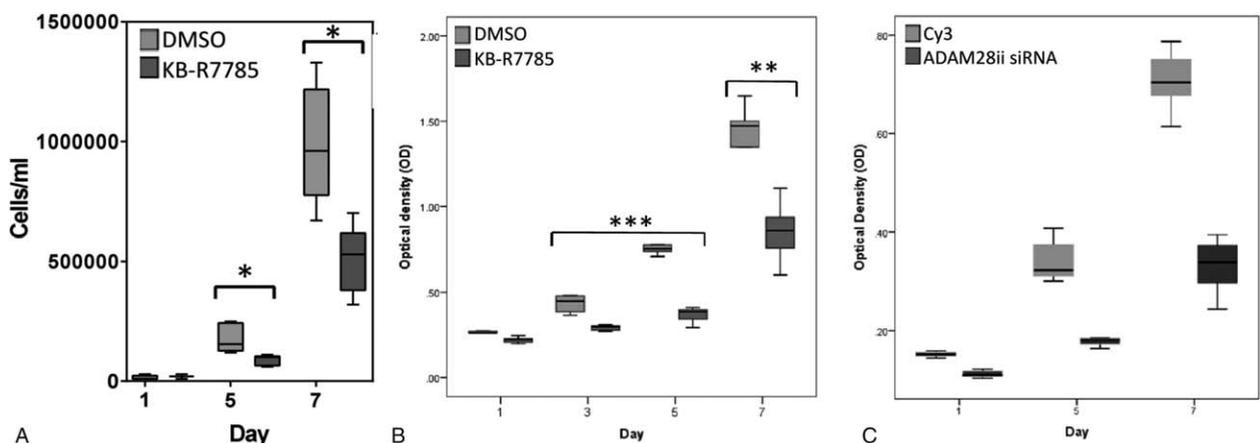

Figure 5. Proliferation of human prostate cancer cells is reduced when ADAM28 is pharmacologically inhibited by KB-R7785 or silenced by siRNA transfection. (A) Proliferation (cells/mL) of DU145 cells treated with KB-R7785 (5 μ M) or DMSO (vehicle control) over a time course of 7 days, and (B) proliferation (optical density at 490 nm) of LNCaP cells treated with KB-R7785 (1 μ M) or DMSO (vehicle control) over 7 days. * $P < 0.006$, ** $P < 0.007$, (***) $P < 0.002$; DMSO vs KB-R7785 for day 3 and 5; Mann-Whitney. Data are presented as a box and whisker plot (A and B), $n=3-8$. (C) Graph depicts proliferation (optical density) of LNCaP cells when transiently transfected with ADAM28 siRNA or Cy3 scrambled control over 7 days. The proliferation of ADAM28ii siRNA transfected LNCaP prostate cancer cells (dark gray) is significantly reduced when compared to the Cy3 scrambled control (light gray) for all time-points. All P values < 0.000004 ; $n=7-8$. Data are presented as a box and whisker plot. ADAM = a disintegrin and metalloproteinase, DMSO = dimethyl sulfoxide, siRNA = short-interfering RNA, SEM = standard error of mean.

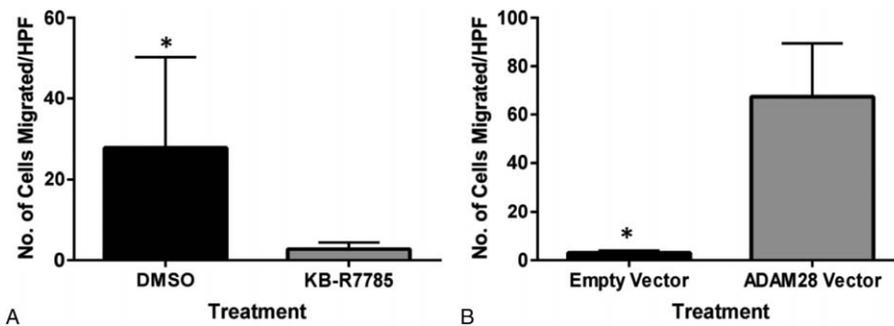

Figure 6. Human prostate cancer cell migration is reduced with ADAM28 inhibition and increased with ADAM28 overexpression. (A) Cell count for LNCaP cells showing that human prostate cancer cell migration is significantly reduced with ADAM28 inhibition by KB-R7785 (10 μ M). (B) Normal epithelial prostate RWPE1 cells exhibit significantly heightened migration when transfected with an ADAM28 expression vector when compared to cells transfected with empty vector. All cell counts were averaged from 5 high power fields of view (HPF). Data are represented as mean \pm SEM, * P < 0.05; n = 5/treatment for (A) and n = 15/treatment for (B). ADAM = a disintegrin and metalloproteinase, HPF = high powered field, SEM = standard error of mean.

human prostate carcinoma cells. Collectively, these findings suggest that ADAM28 may promote the pathogenesis of prostate cancer via proliferation and migration. Thus, successful therapeutic targeting of ADAM28 to inhibit its activity could be a beneficial approach in prostate cancer.

Our team previously elucidated that overexpression of ADAM28 mediated breast carcinoma cell proliferation through the liberation of IGF-I after proteolysis of IGFBP3.^[23] In a prostate cancer setting, IGF-I is a powerful mitogenic factor and may promote the proliferation of prostate carcinoma cells.^[34] Based on these findings, the hypothesis that ADAM28 may play a key role in cell proliferation in human prostate carcinomas was formulated. In our current study, we found that IGF-I liberation is increased when ADAM28 is overexpressed. We propose that this may be via ADAM28-mediated proteolysis of IGFBP3 on prostate carcinoma cells as indicated in Fig. 4A.

The results in the present study indicated that inhibition of ADAM28 by KB-R7785 significantly reduced proliferation and migration of human prostate carcinoma cells compared to control cells. Although KB-R7785 has been shown to completely inhibit ADAM28 activity,^[18] it does have off-target effects on ADAM12.^[9,35] Interestingly, ADAM12 has been shown to be essential for tumor development and progression in a mouse model of prostate cancer.^[36] Thus, in the studies using KB-R7785, some of the functional effects observed could be due to combined blockade of ADAM28 and ADAM12. Future studies will delineate these effects by knocking down ADAM12 expression in prostate cancer or alternatively through the use of an ADAM12 neutralizing antibody that would specifically block the active site of ADAM12 in functional studies. Although an important line of enquiry regards ADAM12, our data using siRNA against ADAM28 and ADAM28 overexpression, validates ADAM28's pathogenic role in prostate cancer.

Several studies have implicated the proinflammatory cytokine, IL-6, in prostate cancer cell proliferation and migration.^[37-40] In our study, ADAM28 overexpression did not influence the level of IL-6 secretion from human prostate cancer cells. Therefore, IL-6 is not a fundamental driver of ADAM28-mediated proliferation and migration of human prostate cancer cells.

This initial study of ADAM28 and prostate cancer raises several questions, including how ADAM28 is regulated in prostate cancer and its mechanism of action. A recent study by our team has verified that the oncogene Src induces ADAM28 expression.^[41] The oncogene Src is involved in regulating cellular proliferation, survival, migration, invasion, metastasis, and

angiogenesis.^[41-45] In addition, we have shown that ADAM28 cleaves IGFBP3 to liberate IGF-I, which in part contributes to carcinoma cell proliferation in breast cancer.^[23] ADAM28 also promotes VEGF₁₆₅ bioavailability by digestion of the VEGF₁₆₅/CTGF complex.^[24] Furthermore, anti-apoptosis of carcinoma cells within blood vessels is due in part to ADAM28 degrading VWF, enabling them to bypass VWF-induced apoptosis.^[25] Thus, these mechanisms could be operative in prostate cancer.

Numerous studies have highlighted a strong correlation between the metabolic syndrome and prostate cancer stage.^[46,47] Interestingly, our group has demonstrated that ADAM28 is significantly elevated with the metabolic syndrome.^[20] There is mounting evidence that prostate cancers are more aggressive in men with the metabolic syndrome than in men without.^[46-51] Interestingly, in our current clinical study, ADAM28 expression in prostate biopsies appeared greater in patients with prostate cancer (Fig. 1). It is possible, therefore, that expression of ADAM28 may be greater in men with the metabolic syndrome and prostate cancer.

In unpublished microarray data from a PhD dissertation,^[52] it was shown that DHT treatment of LNCaP cells resulted in a 20-fold increase in ADAM28 mRNA expression. We now show that DHT treatment of LNCaP cells increases ADAM28 protein expression 3-fold compared to control cells (Fig. 2). Combined, these results suggest that DHT promotes elevated ADAM28 protein expression in LNCaP cells at the transcriptional level.

In conclusion, we have shown for the first time that ADAM28 is overexpressed in human prostate cancer and is involved in driving the proliferation and migration of human prostate carcinoma cells. Importantly, its activity can be inhibited readily by a small molecule inhibitor, suggesting that it may be possible to consider reduction of ADAM28 expression as a new therapeutic strategy in prostate cancer. Further work with validation in preclinical models will provide additional insight into this exciting possibility.
